This work is a cooperation with Dr. Eric Terrill (SIO Scripps), Dr. Lyle Hibler (PNL) and Mark Moline (CalPoly) who are funded separately.

### **LONG-TERM GOALS**

The long-term goal of this effort is to demonstrate the applicability and performance of the Delft3D hydrodynamic/morphodynamic software system to the case of the hydrodynamics and contaminants dispersal and advection. Delft3D has until now been applied extensively to strongly astronomical, wind and wave-forced (shelf sea and nearshore) conditions but not to the weakly-forced conditions such as occur off the California coast. This is of interest to the Navy because of naval operations and the presence of a Navy SEAL training ground just north of the Tijuana River outlet.

In a separate task, the performance of Deltares' river model SOBEK is evaluated for the case of the Pearl River (MS,LA), also of interest to the Navy with respect to training grounds near Stennis Space Center (MS).

### **OBJECTIVE**

The objective of this study is to demonstrate the capabilities of the Delft3D hydrodynamic system by developing a multi-domain (nested) cascade of models ranging from the Southern California Bight scale to the nearshore area around the Tijuana River mouth and Imperial Beach. The model is to be driven with boundary conditions from a larger ocean shelf model (wind, tides, salinity, temperature, etc.) for a number of rainfall events (scale of days and weeks), and to be validated against measured data inside the domain.

An analysis will be made of what conditions determine the trapping and mixing of the plume inside the surfzone and/or the propagation of the plume through the breakers and onto the coastal shelf, and – through a data denial study – what physical processes are important.

For the Pearl River, a demonstration will be given of the performance of the SOBEK river model.

Report Documentation Page			Form Approved OMB No. 0704-0188		
Public reporting burden for the collection of information is estimated to average 1 hour per response, including the time for reviewing instructions, searching existing data sources, gathering and maintaining the data needed, and completing and reviewing the collection of information. Send comments regarding this burden estimate or any other aspect of this collection of information, including suggestions for reducing this burden, to Washington Headquarters Services, Directorate for Information Operations and Reports, 1215 Jefferson Davis Highway, Suite 1204, Arlington VA 22202-4302. Respondents should be aware that notwithstanding any other provision of law, no person shall be subject to a penalty for failing to comply with a collection of information if it does not display a currently valid OMB control number.

## **APPROACH**

The work is divided into 4 tasks

1. Application of the Delft3D model to the San Diego Bay and coastal region
2. Enhancement of the Delft3D system for operational use
3. Pearl River modeling using SOBEK
4. Development of beta-version of San Diego Delft3D model in nowcast/forecast model

## **WORK COMPLETED**

1. Application of the Delft3D model to the San Diego Bay and coastal region

We have set up a Delft3D sea shelf model, coupled it with a larger-scale model and/or data to provide boundary conditions, including flow boundary conditions and solar radiation. In this way the hydrodynamics of the eddies in the San Diego Bight can be simulated. We use point-source contaminants at the Tijuana River Mouth as input in order to perform simulations of the plume contaminant dispersal and water quality conditions on the San Diego Bight. Specifically, we performed 1-month model simulations at the time of rainfall events (February 2009) to analyze model success at simulating local processes.

Only recently COAMPS and NCOM data has become available for this period which will be used to drive the already set up model. We will show the deterioration of the performance of the model through a data-denial study. will be analyzed in order to determine the optimal input of data. Impacts of mixing of the contaminants across the surf zone will be examined. It is expected that in high-surf, in combination with the low river jet momentum conditions, the plume will be trapped within the surf. In contrast, it is expected that in higher river jet momentum conditions, the plume will quickly cross the surf. Additional complexity can occur when high shear is present between the wave-driven long-shore currents within the surf and offshore wind/tidal/pressure gradient forced currents move in opposite directions. Scientific or technological objectives of this effort.

In order to do the analysis a “drifter” code modification has been made in the code which allows numerical drifters to move horizontally in water column along a prescribed path in order to simulate REMUS trajectories. At each horizontal position all variables in the entire vertical will be stored. Given a known vertical position of the instrument the local value of any variable can be retrieved from this column of data

2. Enhancement of the Delft3D system for operational use

We have implemented a roller-model routine in Delft3D-FLOW, which is able to calculate the wave directions independently of SWAN on the FLOW grid. This module has been tested extensively.

This calendar year a mass balance diagnostics module will be added to the Delft3D code.

3. Pearl River modeling using SOBEK

Three visits have been made to NRL-Stennis to demonstrate the capabilities of the SOBEK model, and to make an implementation of the river shed using available online data and discharge events.

The model set-up is conducted with the two hydrodynamic modules “Flow” (1D) and “Overland Flow” (2D). For demonstrating the range of possible modelling options in the software, we set-up different models: i) 1D only model, ii) 2D only model, iii) a combined 1D2D model. Results are still forthcoming.

#### 4. Development of beta-version of San Diego Delft3D model in nowcast/forecast mode

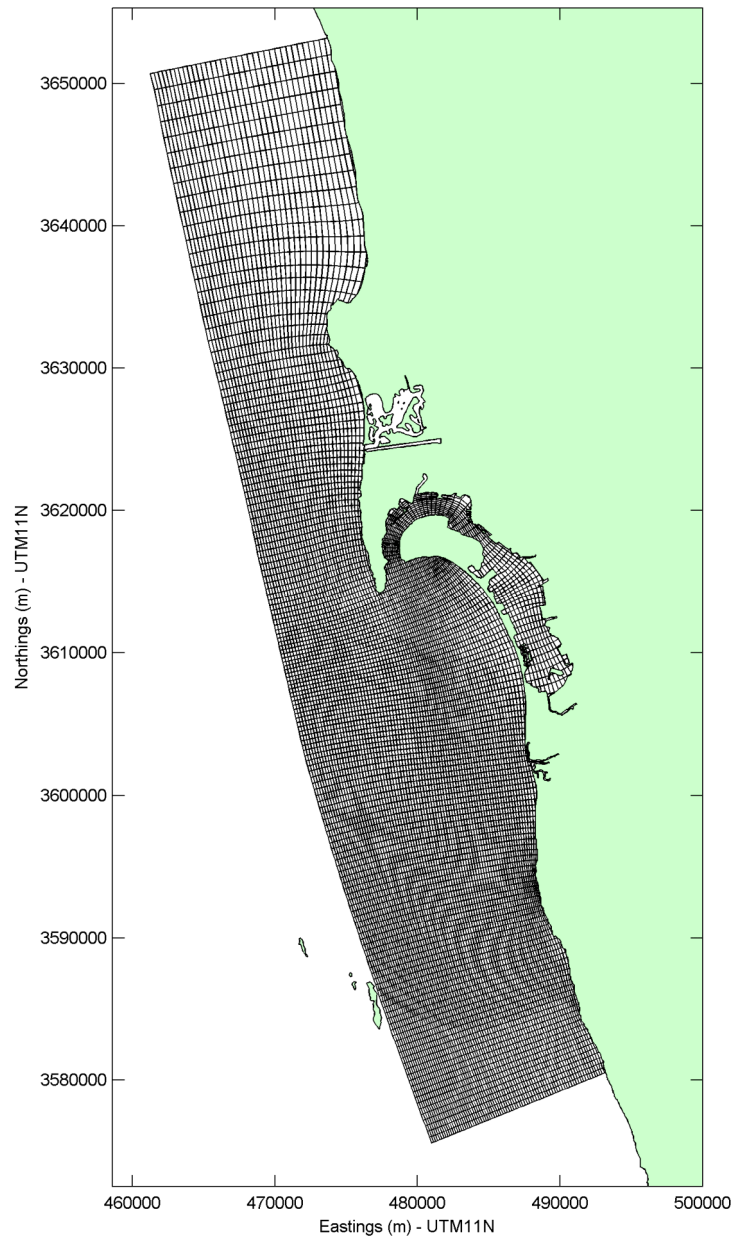

This work is projected for the coming year.

## RESULTS

The curvilinear mesh of the San Diego Bight covers the 30 km stretch of coast from Rosarito (Mexico) to Solana Beach see Figure 1. In order to capture the temperature and salinity stratification in San Diego Bight, it is necessary to run the model in 3D mode. For this purpose, 20 vertical sigma layers are defined. The largest vertical density gradients in the model are expected to occur close to the water surface and this is where the highest vertical resolution is required.

Setting up boundary conditions for the model has turned out to be one of the most challenging problems in this project so far. Multiple configurations of boundary condition types, such as water levels, velocity and Neumann (water level gradient) forcing have been tested along the three (southern, western and northern) open boundaries. The application of water level boundaries in the San Diego Bight model often gives rise to large instabilities in the form of high velocity water jets entering the model domain. It is thought that the strong vertical density variation in combination with relatively weak forcing agents (weak tidal currents, low wind velocities) causes these instabilities. The jets cause unrealistic vertical mixing and large velocities inside the model domain. Using current and Neumann boundaries conditions along the lateral boundaries generally causes unrealistic upwelling close to the shore.

An important finding is that only the use of Riemann (weakly-reflective) boundaries yielded both stable and realistic results. Although these are more cumbersome to set up (one needs both normal velocities and water levels at each boundary) and to some extent cause some loss of control over the water level inside the model domain.

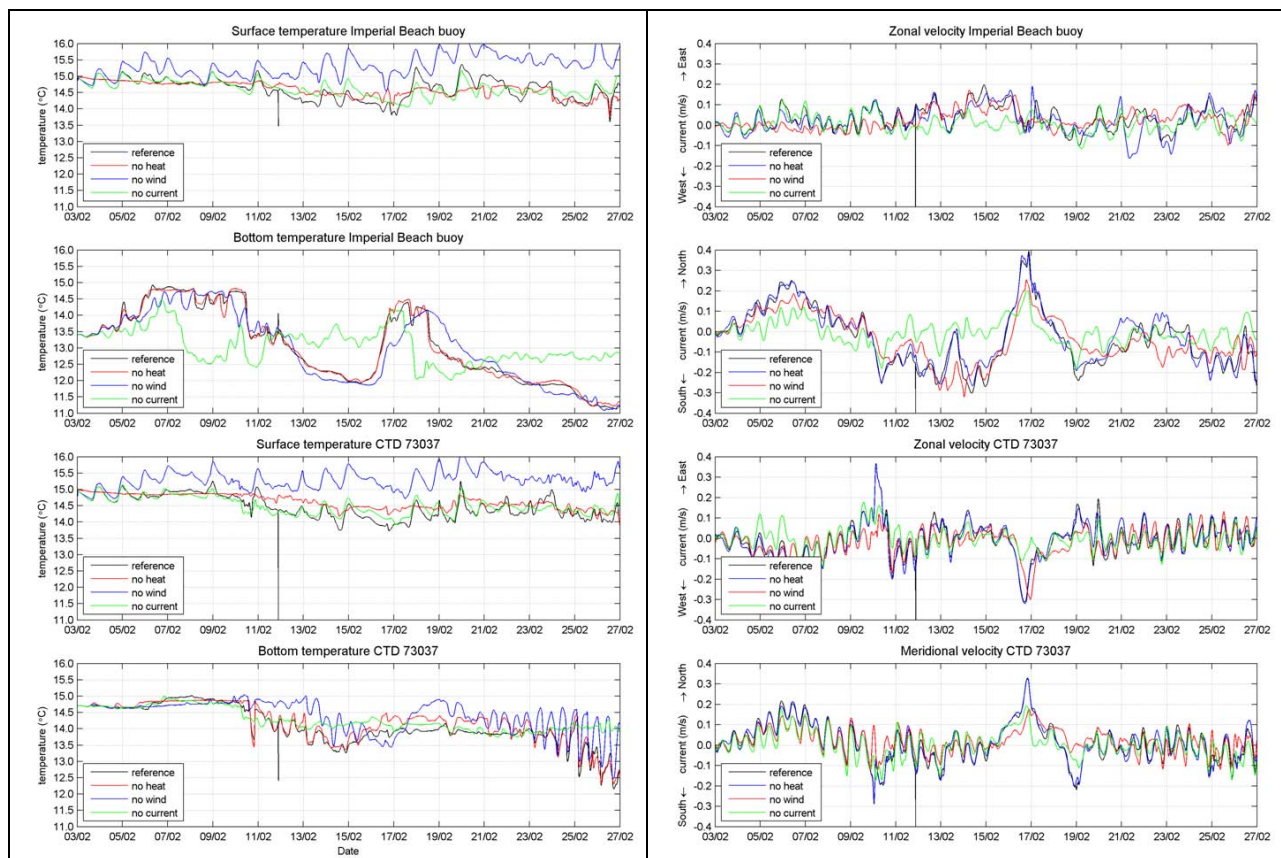

***Figure 1. Computational grid San Diego Bight***

It is important to get an estimate of what the model's sensitivity to different input parameters. For this purpose, a sensitivity analysis has been carried out in which the following changes have been made with respect to a reference simulation

- No wind
- No heat exchange with the atmosphere
- No currents on the southern boundary

Results are shown in the following figure and indicate that it is important to have wind forcing , heat exchange and currents on the boundary all turned on in the model, i.e. no process is dominant.

## IMPACT/APPLICATIONS

The model results so far show that the Delft3D model is capable of simulation the essential processes in the San Diego Bight and can be forced by an outer model, and wind forcing. This tool has the potential to deliver real time forecasting/nowcasting capabilities in this region.

## TRANSITIONS

The Delft3D model software and code is accessible to ONR under the existing DELFT3D license of contract N00014-02-C-075, dated October 3, 2002.

## RELATED PROJECTS

This work is a cooperation with Dr. Eric Terrill (SIO Scripps), Dr. Lyle Hibler (PNL) and Mark Moline (CalPoly) who are funded separately.
